# Standard Penetration Test

## Advantages

- Obtain Sample + Number
- Simple & rugged device at low cost
- Suitable in many soil types
- Can perform in weak rocks
- Available (worldwide)

## Disadvantages

- Obtain Sample + Number
- Energy inefficiency problems
- Discontinuous - only taken every 5 feet (1.5 m)
- Disturbed sample (index tests only)
- Crude number for analysis
- Not applicable in soft clays and silts
- High variability and uncertainty

## Disadvantage of SPT (Idriss & Boulanger 2008)

Figure 57. An excavation face showing the interlayering of sand, gravelly sand, and sandy gravel in an alluvial deposit and the portion of the deposit that would be observed via SPT samples at 1.5-m intervals.

# SPT-N Corrections

$$N_{60} = C_b C_r N \left( \frac{E_m}{60} \right) \quad (2.4)$$

where  $N_{60}$  = standard penetration test  $N$  value corrected for field testing procedures.

$C_b$  = borehole diameter correction ( $C_b = 1.0$  for boreholes of 65 to 115 mm diameter, 1.05 for 150 mm diameter, and 1.15 for 200 mm diameter hole).

$C_r$  = rod length correction ( $C_r = 0.75$  for up to 4 m of drill rods, 0.85 for 4 to 6 m of drill rods, 0.95 for 6 to 10 m of drill rods, and 1.00 for drill rods in excess of 10 m).

$N$  = measured standard penetration test  $N$  value

$E_m$  = hammer efficiency in percent, as described later

**Correction of  $N$  Value for Field Testing and Overburden Pressure.** For geotechnical earthquake engineering, such as liquefaction analyses, the standard penetration test  $N_{60}$  value (Eq. 2.4) is corrected for the overburden soil pressure, also known as the effective overburden pressure or the vertical effective stress ( $\sigma'_{vo}$ ). The vertical effective stress will be discussed in Sec. 4.4. When a correction is applied to the  $N_{60}$  value to account for the vertical effective stress, these values are referred to as  $(N_1)_{60}$  values. The procedure consists of multiplying the  $N_{60}$  value by a correction  $C_N$  in order to calculate the  $(N_1)_{60}$  value. Figure 2.20 presents a chart that is commonly used to obtain the correction factor  $C_N$ . Another option is to use the following equation:

$$(N_1)_{60} = C_N N_{60} = \left( \frac{100}{\sigma'_{vo}} \right)^{0.5} N_{60} \quad (2.5)$$

where  $(N_1)_{60}$  = standard penetration test  $N$  value corrected for both field testing procedures and overburden pressure

$C_N$  = correction factor to account for the overburden pressure. As indicated in Eq. 2.5,  $C_N$  is approximately equal to  $(100/\sigma'_{vo})^{0.5}$  where  $\sigma'_{vo}$  is the vertical effective stress, in kPa. Suggested maximum values of  $C_N$  range from 1.7 to 2.0 (Youd and Idriss, 1997, 2001).

$N_{60}$  = standard penetration test  $N$  value corrected for field testing procedures. The  $N_{60}$  is calculated by using Eq. 2.4.

## DILATANCY CORRECTION

- Terzaghi and Peck (1967) recommended the following correction-

$$N_c = 15 + \frac{1}{2} (N_R - 15)$$

Where;

$N_c$  - Corrected Penetration Number

$N_R$  - Recorded Value

- If  $N_R \leq 15$  ;  $N_c = N_R$

*Table 2. Borehole, Sampler and Rod Correction Factors*

Factor	Equipment Variables	Value
Borehole diameter factor, $C_B$	2.5 - 4.5 in (65 - 115 mm)	1.00
	6 in (150 mm)	1.05
	8 in (200 mm)	1.15
Sampling method factor, $C_S$	Standard sampler	1.00
	Sampler without liner (not recommended)	1.20
Rod length factor, $C_R$	10 - 13 ft (3 - 4 m)	0.75
	13 - 20 ft (4 - 6 m)	0.85
	20 - 30 ft (6 - 10 m)	0.95
	> 30 ft (> 10 m)	1.00

Adapted from Skempton (1986).

# SPT-N Correlations

**TABLE 2.6.** Correlation between  $(N_1)_{60}$  and Density of Sand

$(N_1)_{60}$ (blows per foot)	Sand density	Relative density $D_r$ , percent
0–2	Very loose condition	0–15
2–5	Loose condition	15–35
5–20	Medium condition	35–65
20–35	Dense condition	65–85
Over 35	Very dense condition	85–100

Source: Tokimatsu and Seed (1987).

**Table 35.9** Relationship Between SPT ( $N$ ), Relative Density ( $D_r$ ), and Angle of Internal Friction ( $\phi$ ) (cohesionless soils)

type of soil	SPT, $N$	relative density, $D_r$	angle of internal friction, $\phi$	
			Peck, et al., 1974	Meyerhof, 1956
very loose sand	< 4	< 0.02	< 29	< 30
loose sand	4–10	0.2–0.4	29–30	30–35
medium sand	10–30	0.4–0.6	30–36	35–40
dense sand	30–50	0.6–0.8	36–41	40–45
very dense sand	> 50	> 0.8	> 41	> 45

# SPT-N Correlations

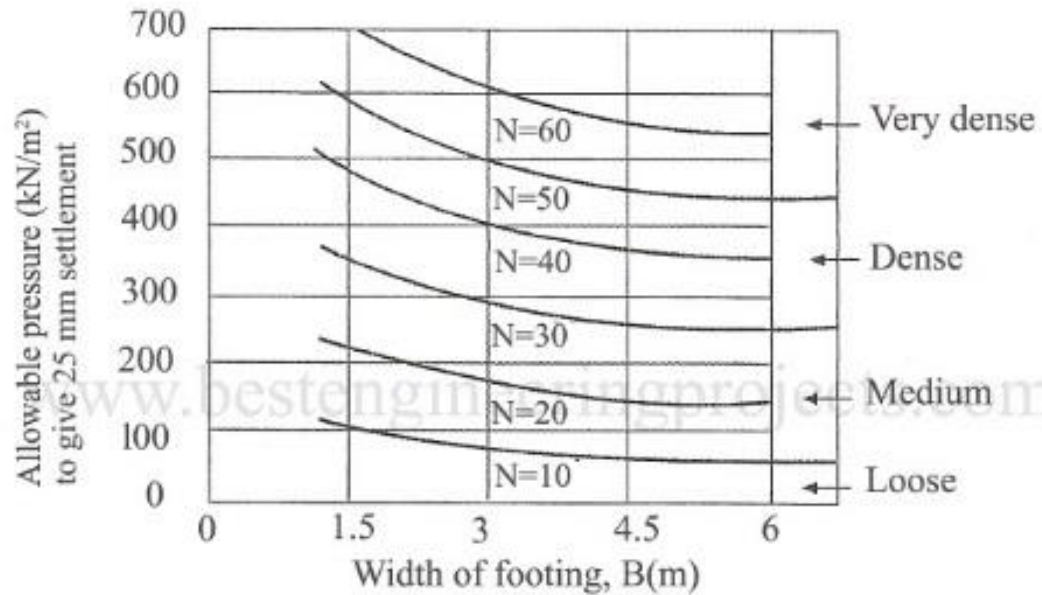

Fig 1 Correlation of Allowable Bearing Pressure to Give 25 mm Settlement to SPT 'N' Value after Terzaghi and Peak (1948)

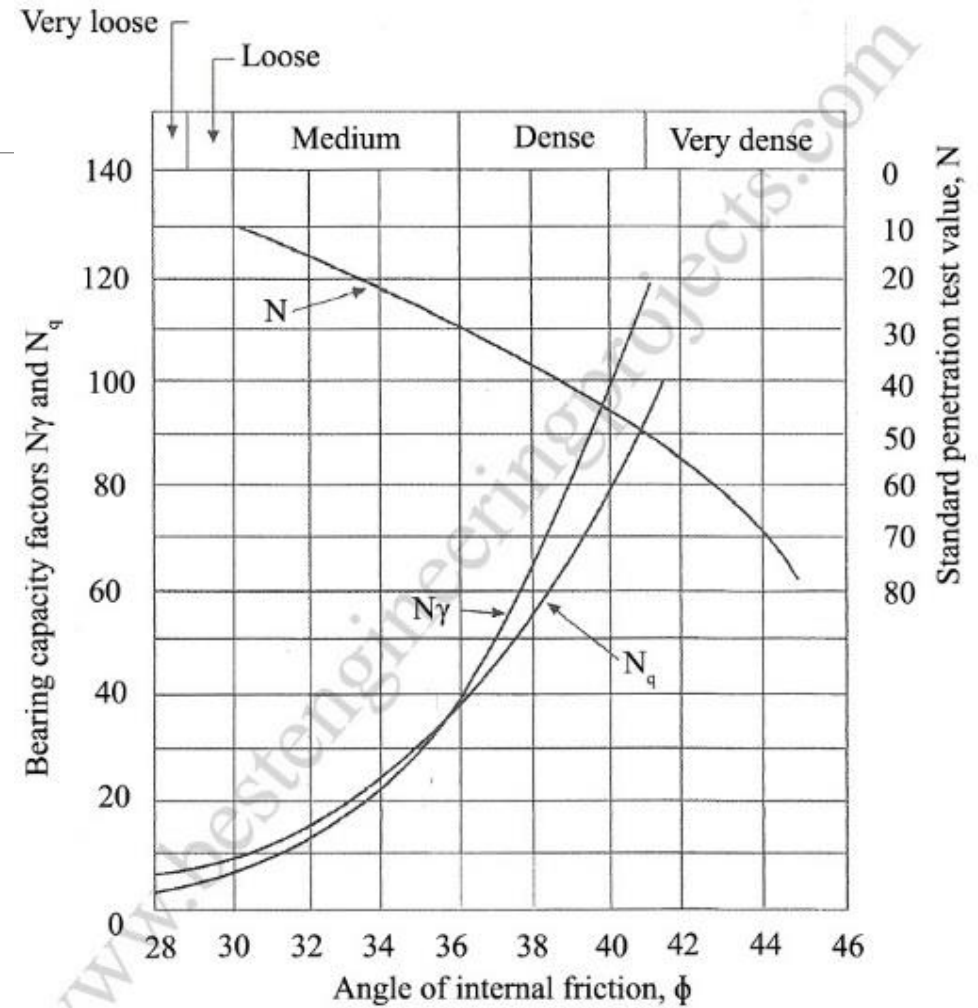

Fig 2 Relationship between SPT 'N' Value and  $\phi$ ,  $N_q$  and  $N_\gamma$  after peak, Hanson and Thornburn (1974)

Figure 7. Values of friction angle  $\phi'$  for clays of various compositions as reflected in plasticity index (Terzaghi, Peck and Mesri, 1996)

# SPT-N Correlations

N Value	Friction Angle, $\phi'$ (Deg.)	Relative Density, $D_r$ (%)	Description
Less than 4	25 - 28	Less than 15	Very loose
4 - 10	29 - 32	15 - 60	Loose
10 - 30	33 - 35	60 - 75	Medium
30 - 50	36 - 40	75 - 90	Dense
Over 50	41 - 45	Over 90	Very dense

N Value	Unconfined Compression Strength ( $\text{kg}\cdot\text{cm}^{-2}$ )	Consistency
Less than 2	Less than 0.25	Very soft
2 - 5	0.25 - 0.50	Soft
5 - 9	0.50 - 1.00	Medium
9 - 17	1.00 - 2.00	Stiff
17 - 33	2.00 - 4.00	Very stiff
Over 33	Over 4.00	Hard

### Correlation between N and Relative Density $D_r$

- correlation between  $N_{60}$  and Relative Density of Granular Soil

$$D_r(\%) = \left[ \frac{N_{60} \left( 0.23 + \frac{0.06}{D_{50}} \right)^{1.7}}{9} \left( \frac{1}{\frac{\sigma'_o}{p_a}} \right) \right]^{0.5} \quad (100)$$

General

$$D_r = \left\{ \frac{N_{60}}{\left[ 17 + 24 \left( \frac{\sigma'_o}{p_a} \right) \right]} \right\}^{0.5}$$

For Clean sand only

where

$D_r$  = relative density

$\sigma'_o$  = effective overburden pressure

$D_{50}$  = sieve size through which 50% of the soil will pass (mm)

$p_a$  = atmospheric pressure ( $\approx 100 \text{ kN/m}^2$ ),

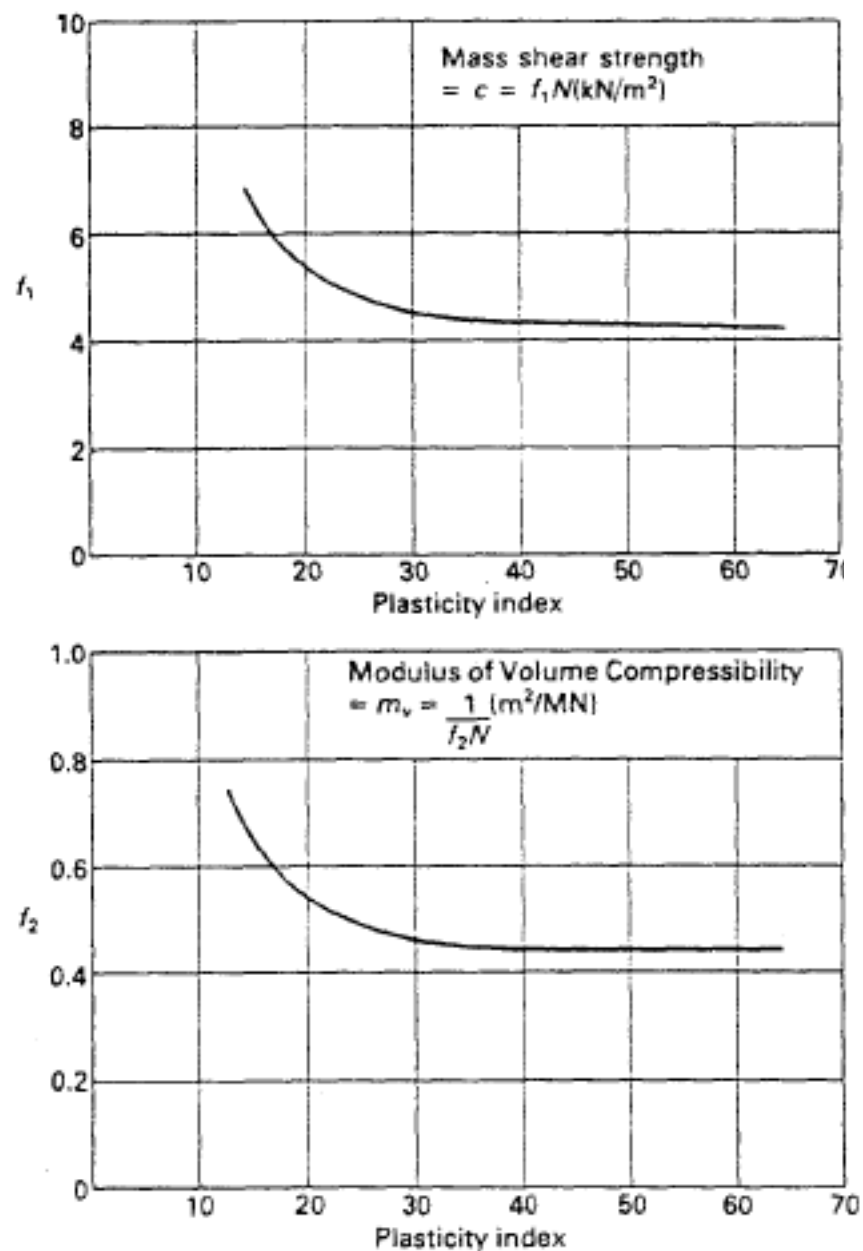

Table 4. Stroud (1989) recommendation for  $c_u$  ( $c_u = f_1 * N_{60}$ )

Soil Type	$f_1$ (kN/m <sup>2</sup> )
Overconsolidated clays IP = 50%	4.5
Overconsolidated clays IP = 15%	5.5
Insensitve weak rocks $N_{60} < 200$	5.0

Figure 8. Relationship between Mass Shear Strength, Modulus of Volume Compressibility, Plasticity Index, and SPT-N values ( after Stroud, 1975)

Figure 9. Approximate Correlation between Undrained Shear Strength and SPT-N values (After Sowers, 1979)

TABLE S-5 Equations for stress-strain modulus  $E_s$  by several test methods  
 $E_s$  in kPa for SPT and units of  $q_c$  for CPT; divide kPa by 50 to obtain ksf. The  $N$  values should be estimated as

$\rightarrow N_{60}$  and not  $N_{70}$  **N55**

Soil	SPT	CPT
Sand (normally consolidated)	$E_s = 500(N + 15)$ $E_s = (15\,000 \text{ to } 22\,000) \ln N$ $E_{s\beta} = (35\,000 \text{ to } 50\,000) \log N$	$E_s = 2 \text{ to } 4q_c$ $E_s^\dagger = (1 + D_r^2)q_c$
Sand (saturated)	$E_s = 250(N + 15)$	
Sand (overconsolidated)	$E_{s\beta} = 18\,000 + 750N$ $E_{s(\text{OCR})} = E_{s(\text{net})} (\text{OCR})^{1/2}$	$E_s = 6 \text{ to } 30q_c$
Gravelly sand and gravel	$E_s = 1200(N + 6)$ $E_s = 600(N + 6) \quad N \leq 15$ $E_s = 600(N + 6) + 2000 \quad N > 15$	
Clayey sand	$E_s = 320(N + 15)$	$E_s = 3 \text{ to } 6q_c$
Silty sand	$E_s = 300(N + 6)$	$E_s = 1 \text{ to } 2q_c$
Soft clay	—	$E_s = 3 \text{ to } 8q_c$
Clay	Using the undrained shear strength $s_u$ in units of $s_u$ $I_p > 30$ or organic $I_p < 30$ or stiff $E_{s(\text{OCR})} = E_{s(\text{net})} (\text{OCR})^{1/2}$	$E_s = 100 \text{ to } 500s_u$ $*E_s = 500 \text{ to } 1500s_u$

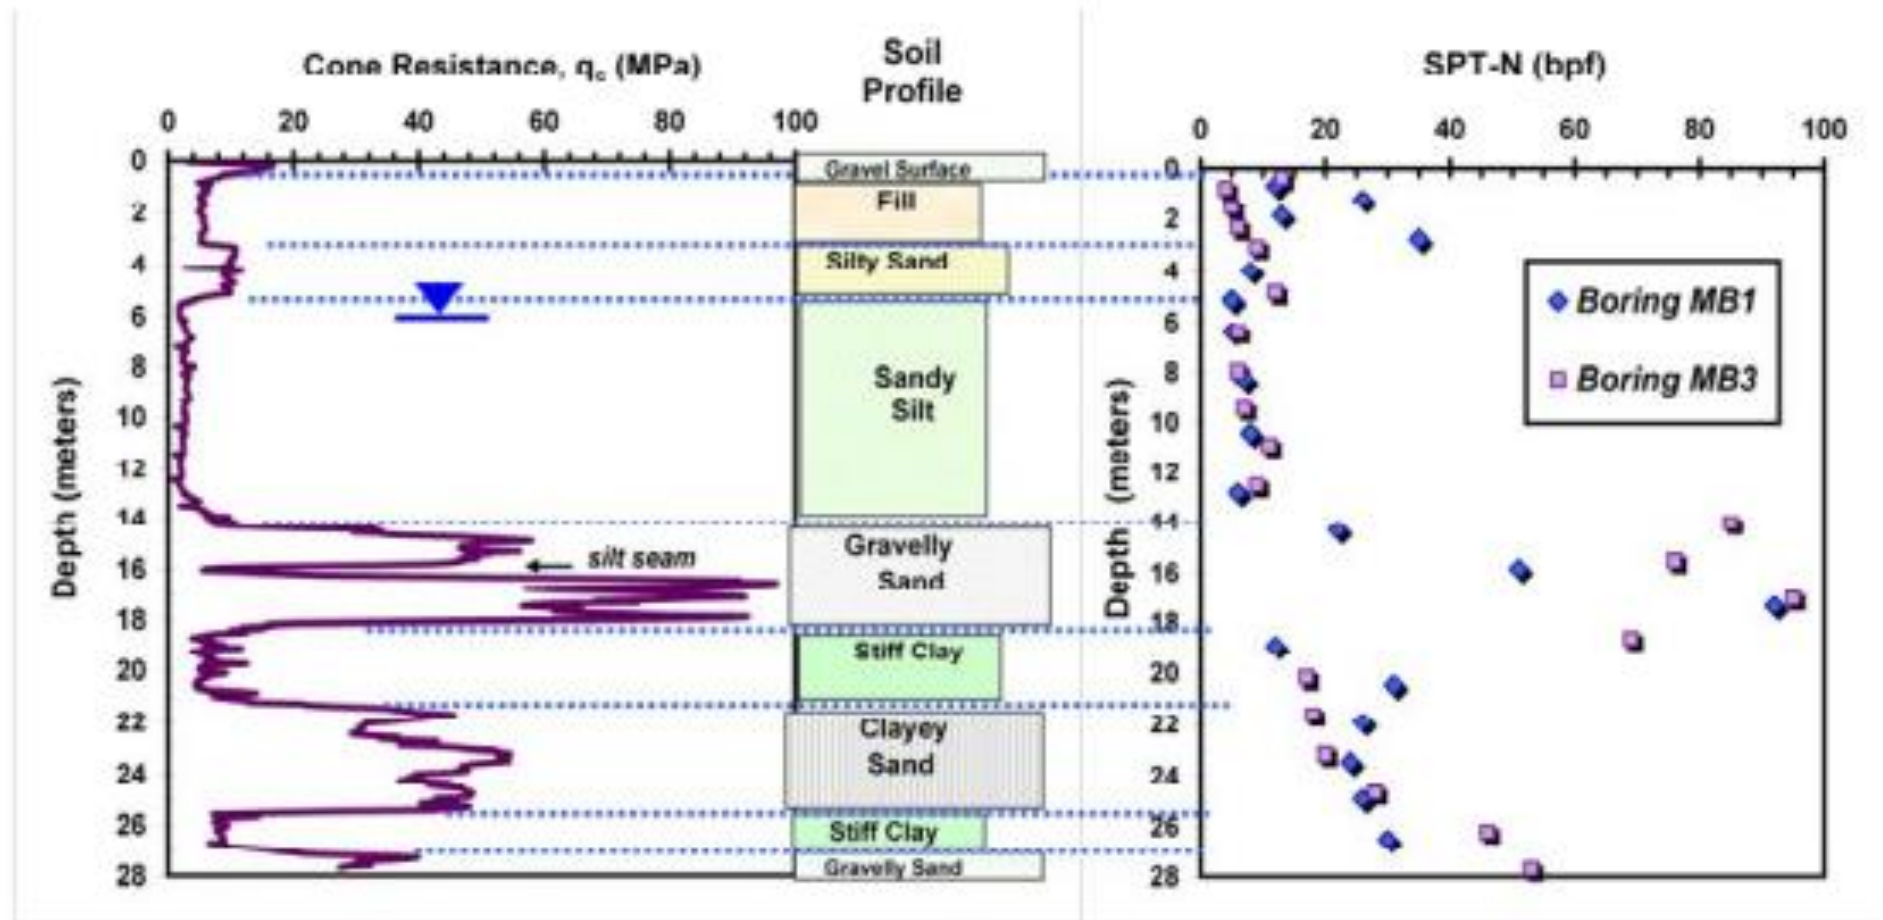

Figure 2. Companion Profile of CPT Cone Tip Resistance and Soil Boring Log with SPT-N values.

## Corrections for Tip and Sleeve Readings

- $d_j$  = diameter geometry (as shown)
- $t_j$  = thickness of friction sleeve
- $u_1$  = measured porewater pressure
- $q_c$  = measured cone tip resistance
- $f_s$  = measured sleeve friction
- $q_t$  = total cone tip resistance
- $f_t$  = total sleeve resistance
- $a_n$  = tip net area ratio from triaxial test
- $b_n$  = sleeve net ratio from triaxial test
- $h_s$  = height of sleeve

### Sleeve Friction:

$$f_t = f_s - (\pi d_2 t_2 u_2 + \pi d_3 t_3 u_3) / (\pi d_c h_s)$$

$$f_t \approx f_s - b_n u_2$$

### Tip Resistance:

$$q_t = q_c + (1 - a_n) u_2$$

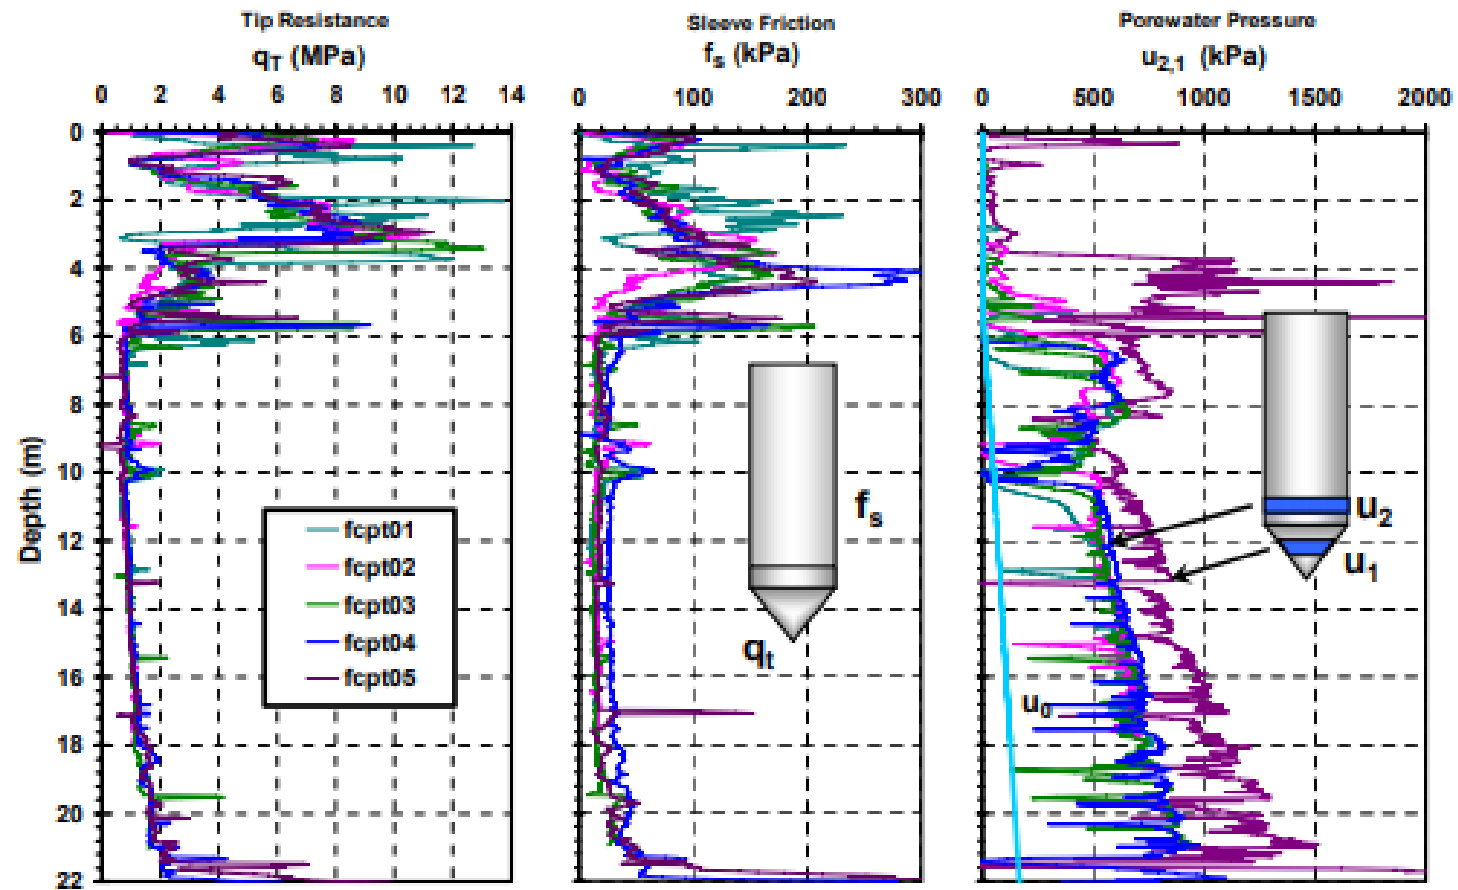

Figure 15. Series of Piezocone Penetration Tests at Northwestern University.

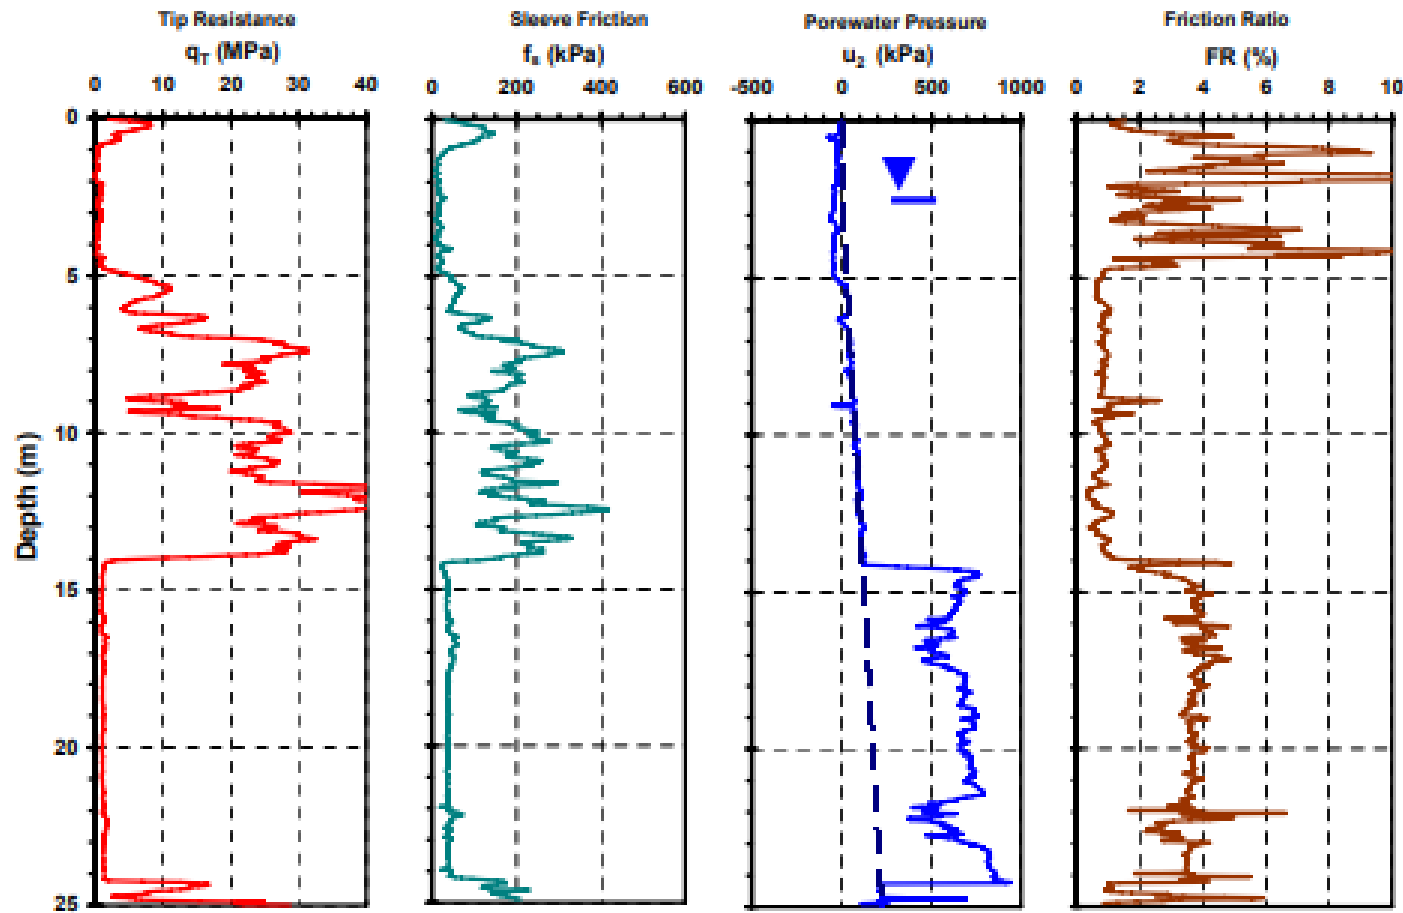

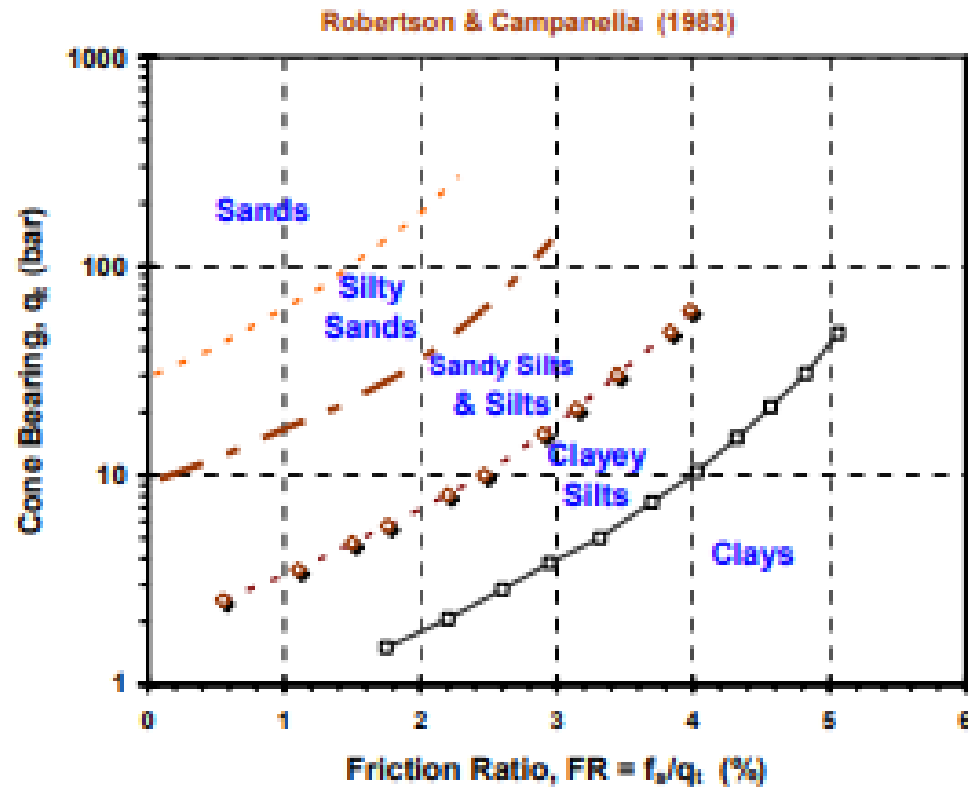

Figure 23. Presentation of CPTu Results, showing (a) Total Cone Tip Resistance, (b) Sleeve Friction, (c) Shoulder Porewater Pressures, and (d) Friction ratio ( $FR = R_f = f_s/q_t$ ) with Depth in Steele, Missouri.

# Determination of $V_s$ Using CPT

---

For uncemented unaged quartzitic sands, Baldi et al. (1989) suggested the shear wave velocity may be evaluated from the following relationship:

$$\text{Sands: } V_s = 277 (q_t)^{0.13} (\sigma_{vo}')^{0.27} \quad (8)$$

where  $V_s$  = shear wave velocity (m/s), and  $q_t$  = corrected cone tip resistance (MPa), and  $\sigma_{vo}'$  = effective overburden stress (MPa), as shown in Figure 28a. For clay soils, Figure 28b shows a generalized interrelationship between shear wave and cone tip resistance for soft to firm to stiff intact clays to fissured clay materials (Mayne & Rix, 1995) that determined:

$$\text{Clays: } V_s = 1.75 (q_t)^{0.627} \quad (9)$$

The relationship was significantly improved for intact clays if both the tip stress ( $q_t$  in kPa) and void ratio ( $e_0$ ) were known in advance.

Of particular interest are interpretative methods that accommodate all types of soils. In one approach, an estimate of the in-situ shear wave velocity can be made from (Hegazy & Mayne, 1995):

$$\text{All Soils: } V_s \text{ (m/s)} = [10.1 \cdot \log q_t - 11.4]^{1.67} [f_s/q_t \cdot 100]^{0.3} \quad (10)$$

where  $q_t$  = tip resistance and  $f_s$  = sleeve resistance are input in units of kPa. The relationship was derived from a database that included sands, silts, clays, as well as mixed soil types, thus is interesting in that it attempts to be global and not a soil-dependent relationship. A similar database from well-documented experimental sites in saturated clays, silts, and sands showed that (Mayne, 2006c):

$$V_s = 118.8 \log (f_s) + 18.5 \quad (11)$$

where  $f_s$  is in kPa.

Relative Density of Undisturbed (Frozen) Quartz Sands vs. Normalized Cone Tip Resistance.

# Determination of $I_R$ and Bearing Capacity Using CPT

## Rigidity Index

The rigidity index ( $I_R$ ) of soil is defined as the ratio of shear modulus ( $G$ ) to shear strength ( $\tau_{\max}$ ), thus from considerations of cavity expansion and critical-state soil mechanics, the undrained value of rigidity index ( $I_R = G/s_u$ ) can be evaluated directly from the CPTu data (Mayne, 2001):

$$I_R = \exp\left[\left(\frac{1.5}{M} + 2.925\right)\left(\frac{q_t - \sigma_{vo}}{q_t - u_2}\right) - 2.925\right] \quad (43)$$

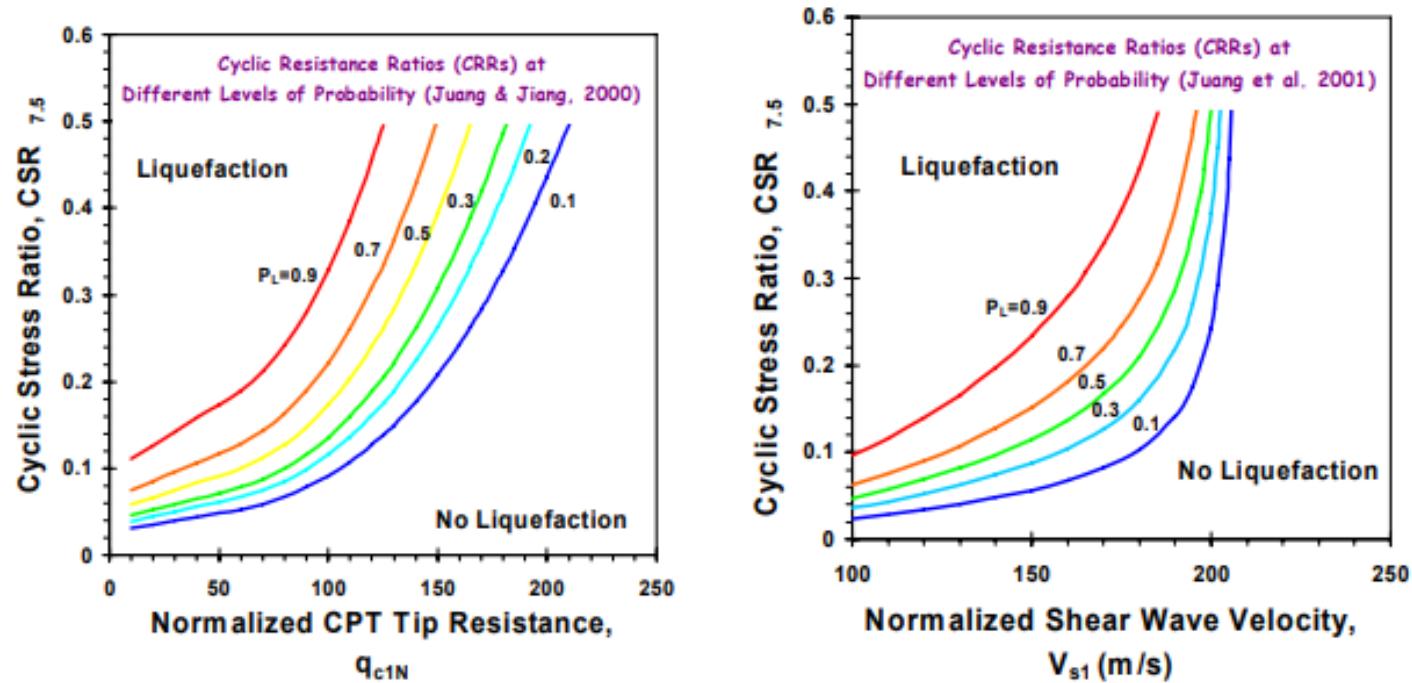

Figure 86. Probabilistic Cyclic Resistance Ratios (CRRs) for Clean Sands based on (a) Cone Tip Resistance and (b) Shear Wave Velocity (after Juang & Jiang, 2000).

Table 8. Estimation of constrained modulus,  $M$ , for clays (Adapted from Sanglerat, 1972)  
(after Mitchell and Gardner, 1975)

$M = 1/m_v = \alpha_m \cdot q_c$		
$q_c < 0.7$ MPa	$3 < \alpha_m < 8$	Clay of low plasticity (CL)
$0.7 < q_c < 2.0$ MPa	$2 < \alpha_m < 5$	
$q_c > 2.0$ MPa	$1 < \alpha_m < 2.5$	
$q_c > 2$ MPa	$3 < \alpha_m < 6$	Silts of low plasticity (ML)
$q_c < 2$ MPa	$1 < \alpha_m < 3$	
$q_c < 2$ MPa	$2 < \alpha_m < 6$	Highly plastic silts and clays (MH, CH)
$q_c < 1.2$ MPa	$2 < \alpha_m < 8$	Organic silts (OL)
$q_c < 0.7$ MPa		Peat and organic clay (P, OH)
$50 < w < 100$	$1.5 < \alpha_m < 4$	
$100 < w < 200$	$1 < \alpha_m < 1.5$	
$w > 200$	$0.4 < \alpha_m < 1$	

w = water content

# Vane Shear Test

## Vane Shear Test

Vane shear is a type of test (ASTM D-2573) that may be used during the drilling operation to determine the in situ undrained shear strength ( $c_u$ ) of clay soils—particularly soft clays. The vane shear apparatus consists of four blades on the end of a rod, as shown in Figure 2.16a. The vanes of the apparatus are pushed into the soil at the bottom of a borehole without disturbing the soil appreciably. Torque is applied at the top of the rod to rotate the vanes. This will induce failure in a soil of cylindrical shape surrounding the vanes. The maximum torque applied can be related to the undrained strength of a clayey soil as

$$T = c_u \pi D^2 \left( \frac{H}{2} + \frac{D}{6} \right)$$

or

$$c_u = \frac{T}{\pi D^2 \left( \frac{H}{2} + \frac{D}{6} \right)} \quad (2.7)$$

# Compressibility Parameters

**Table 5.1** TYPICAL VALUES OF THE COEFFICIENT OF VOLUME COMPRESSIBILITY AND DESCRIPTIVE TERMS USED (AFTER CARTER 1983)

Type of clay	Descriptive term	Coefficient of volume compressibility, $m_v$	
		$\frac{m_v}{MN} = 0.1 \frac{m^2}{kg}$ (m <sup>2</sup> /MN)	(ft <sup>2</sup> /ton)
Heavy over-consolidated boulder clays, stiff weathered rocks (e.g. weathered mudstone) and hard clays	Very low compressibility	<0.05	<0.005
Boulder clays, marls, very stiff tropical red clays	Low compressibility	0.05–0.1	0.005–0.01
Firm clays, glacial outwash clays, lake deposits, weathered marls, firm boulder clays, normally consolidated clays at depth and firm tropical red clays	Medium compressibility	0.1–0.3	0.01–0.03
Normally consolidated alluvial clays such as estuarine and delta deposits, and sensitive clays	High compressibility	0.3–1.5	0.03–0.15
Highly organic alluvial clays and peats	Very high compressibility	>1.5	>0.15

# Compressibility Parameters

**Table 5.2** TYPICAL VALUES OF COMPRESSIBILITY INDEX,  $C_c$  (AFTER HOLTZ AND KOVACS 1981)

Soil	$C_c$
Normally consolidated medium sensitive clays	0.2 to 0.5
Chicago silty clay (CL)	0.15 to 0.3
Boston blue clay (CL)	0.3 to 0.5
Vicksburg Buckshot clay (CH)	0.5 to 0.6
Swedish medium sensitive clays (CL-CH)	1 to 3
Canadian Leda clays (CL-CH)	1 to 4
Mexico City clay (MH)	7 to 10
Organic clays (OH)	4 and up
Peats (Pt)	10 to 15
Organic silt and clayey silts (ML-MH)	1.5 to 4.0
San Francisco Bay Mud (CL)	0.4 to 1.2
San Francisco Old Bay clays (CH)	0.7 to 0.9
Bangkok clay (CH)	0.4

**Table 5.3** SOME PUBLISHED CORRELATIONS FOR COMPRESSION INDICES (AFTER AZOUZ ET AL. 1976)

Equation	Regions of applicability
$C_c = 0.007(LL - 7)$	Remoulded clays
$C_{cr} = 0.208e_0 + 0.0083$	Chicago clays
$C_c = 17.66 \times 10^{-3}w_n^2 + 5.93 \times 10^{-3}w_n - 1.35 \times 10^{-4}$	Chicago clays
$C_c = 1.15(e_0 - 0.35)$	All clays
$C_c = 0.30(e_0 - 0.27)$	Inorganic, cohesive soil; silt, some clay; silty clay; clay
$C_c = 1.15 \times 10^{-2}w_n$	Organic soils-meadow mats, peats, and organic silt and clay
$C_c = 0.75(e_0 - 0.50)$	Soils of very low plasticity
$C_{cr} = 0.156e_0 + 0.0107$	All clays
$C_c = 0.01w_n$	Chicago clays

As summarised by Azouz, Krizek, and Corotis (1976).  
Note:  $w_n$  = natural water content.

Skempton (1944)

$$C_c = 0.007(LL - 10).$$

Terzaghi and Peck (1967)

$$C_c = 0.009(LL - 10).$$
